## Problem 1

Given an undirected graph  $G$ , describe an algorithm that can check if it is bipartite. A graph is bipartite if its vertices are partitioned into two sets  $A$  and  $B$  where all the edges are of the form  $(a,b)$  with  $a$  in  $A$ ,  $b$  in  $B$ .

You can determine if the graph is bipartite by using BFS. Assign one color (let's say black) to the source vertex, which we will put in set  $A$ . Then, color all the neighbors gray, putting them into set  $B$ . Color all the neighbors of those neighbors black and put them into set  $A$ . When we assign colors, if we find a neighbor with the same color as the current vertex, the graph can't be colored with two vertices. This means that the graph isn't bipartite. A bipartite graph is possible if the graph coloring is possible using two colors such that vertices in a set are colored with the same color.

## Problem 2

Do a BFS of the undirected graph with the given adjacency list, where starting vertex is  $x$  and vertices are placed on queue in alphabetic order. Draw the graph.

| Order of Visitation | Queue Contents After Visiting Node |
|---------------------|------------------------------------|
|                     | [x]                                |
| x                   | [t w y]                            |
| t                   | [w y u x]                          |
| w                   | [y u x s]                          |
| y                   | [u x s]                            |
| u                   | [x s]                              |
| x                   | [s]                                |
| s                   | [r]                                |
| r                   | [v]                                |
| v                   | []                                 |

### Problem 3

Given a tree  $T = (V, E)$  compute its diameter, i.e. the longest path between two vertices. Do BFS at a node  $s$ , find the farthest from  $s$  to get a vertex, say  $t$ . Then do BFS from  $t$  to find the farthest from  $t$ . Prove this gives the diameter of the tree. Diameter of a tree is the longest path in the tree.

Assume we have a tree given by  $T = (V, E)$ .

Assume the algorithm finds a vertex  $t$  by performing BFS( $s$ ) on some node  $s$ .

Then, assume it finds another vertex  $r$  by performing BFS( $t$ ) on  $t$ .

It is clear that  $t$  must be a leaf node, since leaf nodes provide the paths with the farthest distance.

It is also clear that  $r$  must be a leaf node for the same reason.

Then,  $d(t, r)$  is the diameter of  $T$ , since it is the longest path between any two leaf nodes.

If the longest path happened to be  $d(s, t)$ , then  $r = s$ .

### Problem 4

Show that in an undirected graph the sum of the degrees of the vertices is twice the number of edges.

Any two points on a connected graph is connected by at least one edge. In an undirected graph, for any two vertices  $v_1$  and  $v_2$  with edges  $e_1, e_2, \dots, e_n$  connecting  $v_1$  and  $v_2$ , then for any edge  $e_i$  there is of degree two. Therefore, for  $n$  edges the number of degrees is  $2n$ . Assume the base case of where there is only two vertices with a single edge connecting them. Then, the sum of the degrees is 2 and there is only 1 edge and therefore the statement holds. Now, assume that it is true for a graph with  $k$  edges and would, therefore have  $2k$  degrees. If another edge is added to the graph, then that increases the number of degrees by 2 and therefore,  $2k + 2 = 2(k + 1)$  which shows that the statement holds true for  $k$  and  $k + 1$ .
